language: JavaScript

TABLE OF CONTENT

Foreword

First, you learnt Javascript syntax by doing CLI exercices.

Then, you used Javascript from inside a web page in order to modify HTML elements.

Now, you will use Javascript to code Backend API with Node.JS and Express.JS in order to learn *modern* Javascript.

As seen during Kick-Off, Node.JS is a runtime environment that executes JavaScript code outside a web browser.

That makes Node.JS on par with PHP language. That's it. Node.JS itself doesn't provide anything for web-development.

You need to use library such a Express.js to do specific web-development. `https://expressjs.com`

PHP and any JavaScript library are forbidden

Installing Express.js

For each code environment, you always use a `package manager` :
- `apt` for ubuntu packages
- `composer` for PHP packages
- `npm` for javascript

When you installed Node.js, it had installed npm command too.
Create a empty folder

```
Terminal
~/C-DEV-115>
```

(`mkdir js_backend && cd js_backend`)

Installing express for this project

```
Terminal
~/C-DEV-115> npm install express --save
```

Step 1

With Express.js create an API based on the SQL database given to you.

Each route must return JSON only. No HTML allowed !

You must implements these routes :

1. `GET /api/movies` this returns only the 20 first movies entry with basic info
2. `GET /api/movies/{id}` this return full info about the movie with the specified id
3. `GET /api/movies/{id}/genres` this return the genre of the movie with the specified id
4. `GET /api/movies/{id}/producers` this return the producer of the movie with the specified id

```
npm install mysql
```

Step 2

From within a .html file, write javascript functions to perform HTTP requests to the backend.

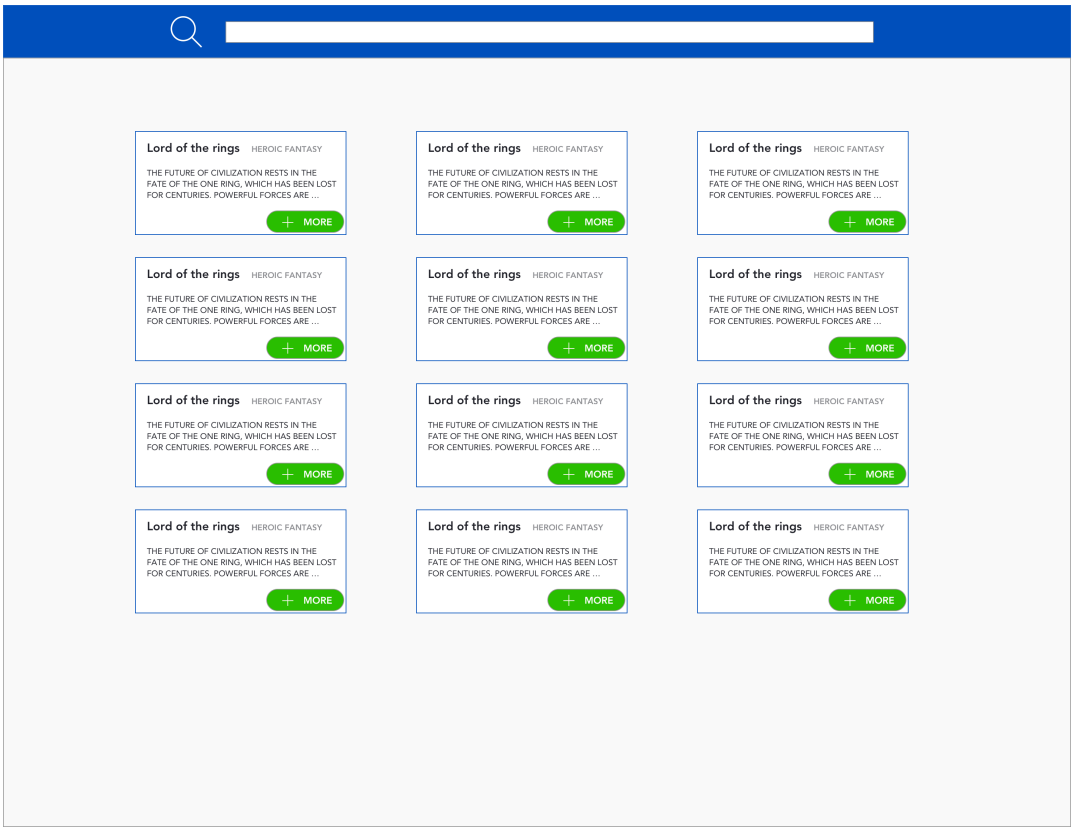
It is mandatory to use javascript's ES6 "Fetch" to do it. You can read this doc : `https://developers.google.com/web/updates/2015/03/introduction-to-fetch#fetch`

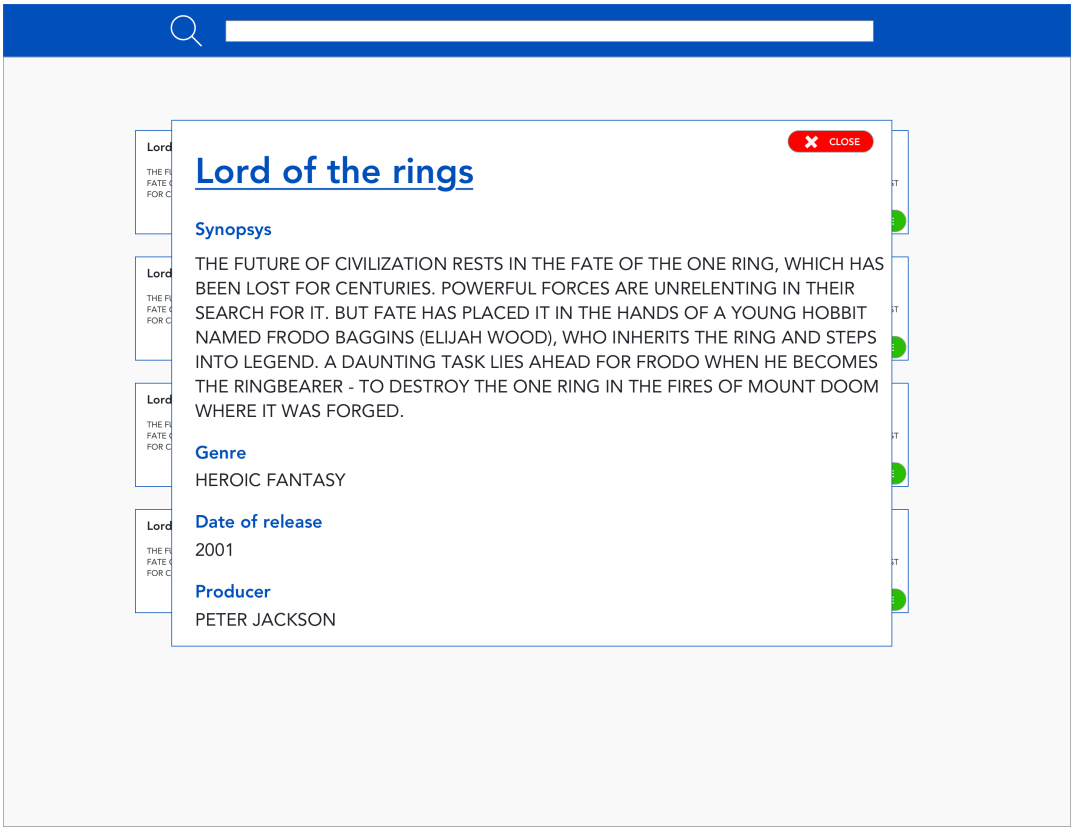
STEP 3

Write basic HTML to display these informations.

You can use any CSS framework (such as bootstrap) to have a better UI

When the user click on MORE from a movie tile, it opens a pop-up window with detailled informations about this movie.

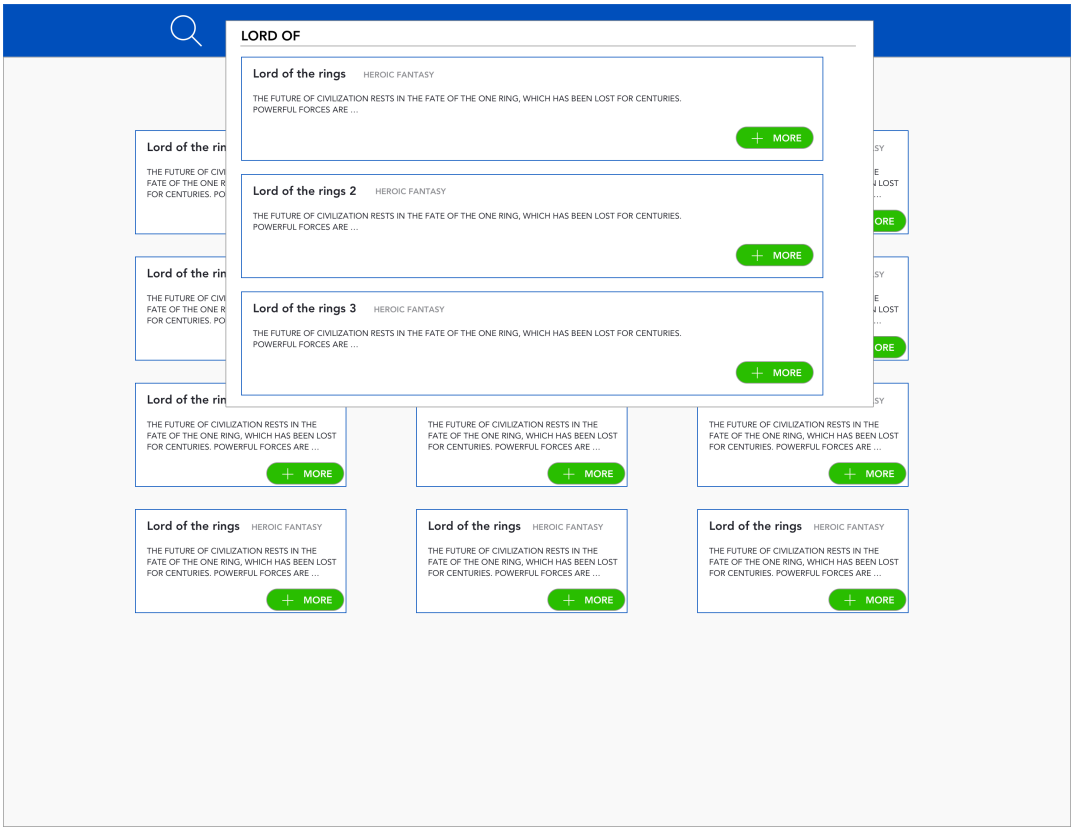




Step 4

In the header of your HTML file, implement a search bar that displays the result without refreshing the web-page (such as http://www.allocine.fr).

It will display at most 10 results.



STEP 5 - BONUS

Implement a `infinite scroll` in the home page.
